Apworks	2.5.4563.21309
Visual Studio	10 SP1 (VS2010 SP1), 11 (VS2012)
.NET Framework	4.0 Full

Overview

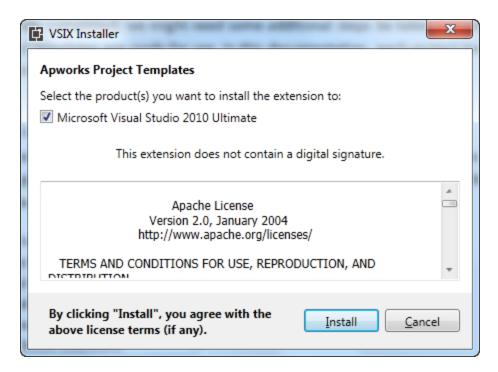

In order to help developers getting started with Apworks application development much faster, from version 2.5, Apworks carries lots of Visual Studio project templates along within its installation package. Since Apworks installer was built with InstallShield LE (Limited Edition), many wonderful functionalities was disabled by its limited license, so after the setup program was successfully completed, we might need some additional steps be taken before the Visual Studio project templates are ready for use. In this documentation, each project template will be introduced and more detailed information is provided.

Installation

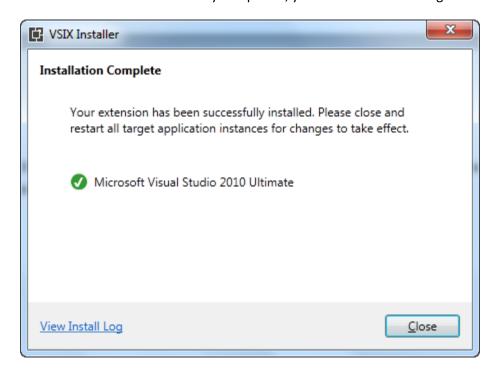

Apworks installer won't install the Visual Studio Extensions (VSE) that contains the project templates automatically, users should install the VSEs manually by accessing the Start menu shortcut under Apworks Framework folder, just like below:

After clicking this menu item, the VSIX Installer will appear, users are able to select the available Visual Studio versions to install.

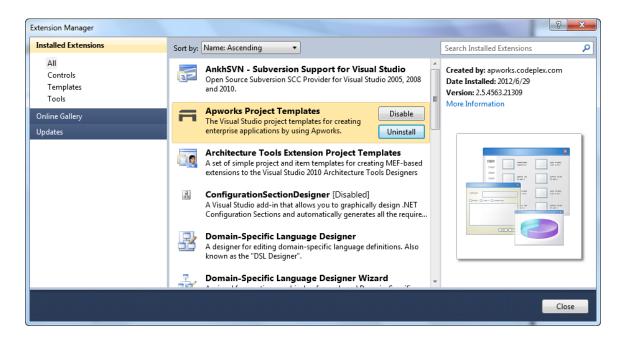

Now start the Visual Studio Extension installation by clicking the Install button on the dialog box, if the installation has successfully completed, you will see the following screen:

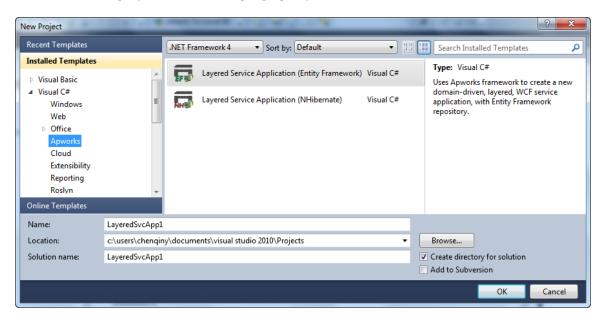

Manage

After the Visual Studio Extension has been installed, you can Enable/Disable the extension by using Visual Studio's Extension Manager dialog box (From Tools -> Extension Manager menu in Visual Studio). You can also uninstall the extension there.

Create Applications with Project Templates

In Microsoft Visual Studio, click File -> New -> Project menu, this will open the New Project dialog box. Under Installed Templates group, under Visual C# category, you can find a sub category named "Apworks", all the Apworks related project templates are available here. Note that Apworks project templates only support Visual C# programming language, so you cannot find this sub category under other language groups.

Select a project template you wish to use, and like creating other types of applications, simply give your solution a name and click OK button. Visual Studio will create the project for you.

Project Templates

In this section, all available project templates will be introduced.

Layered Service Application (Entity Framework)

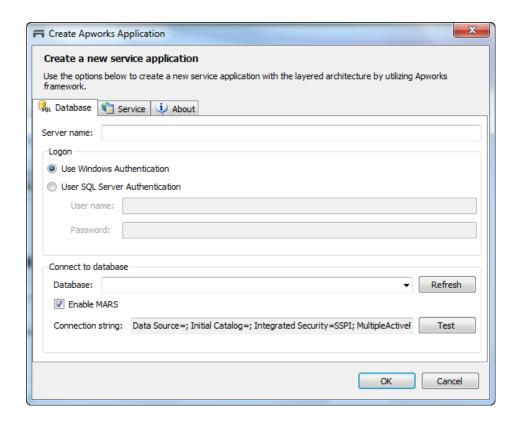

This project template will create a sample service application solution with the traditional layered architecture. The created sample application is based on a very simple scenario: Users are able to maintain their Notes, and it will use the Microsoft ADO.NET Entity Framework as the implementation technology of the repositories.

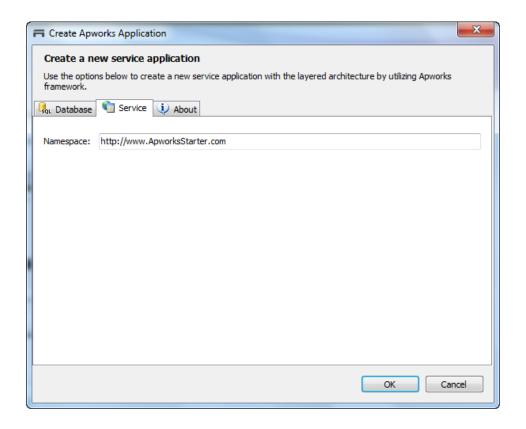

Note that the created application is a WCF service application, the project template doesn't provide any GUI logic to present the sample application. Developers should handle the GUI logic by themselves. This is because GUI development technology grows rapidly and it is hard to make Apworks targeting a specific version of some kind of UI frameworks.

To create a Layered Service Application (Entity Framework), in the New Project dialog, select this template and provide a project name, then click OK and follow the steps below:

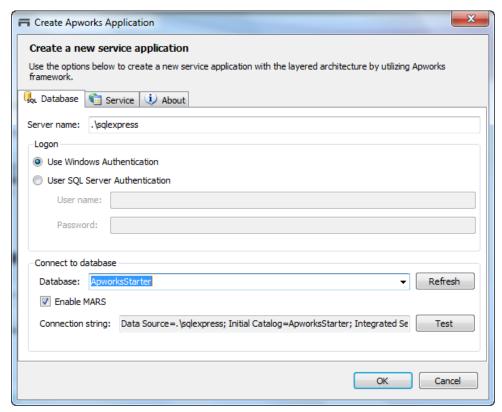

- 1. After OK button is clicked on the New Project dialog, the Create Apworks Application dialog box appears. There are three tabs on this dialog box:
 - Database Provides the database information here, the database will be used
 as the backend data store for the new application. Note that currently this
 project template only supports SQL Server databases. If you want to use other
 databases (Like Oracle, or even NoSQL databases), you can change your
 connection string in the Service project's Web.config file. This is the project
 template's limitation, Apworks framework allows you to use any kind of
 database per your requirement

Services – Provides the WCF service-related configuration here. For now you
only need to specify the Namespace for the service. By default, it will use
http://www.XXXX.com as the Namespace, where XXXX stands for your solution
name

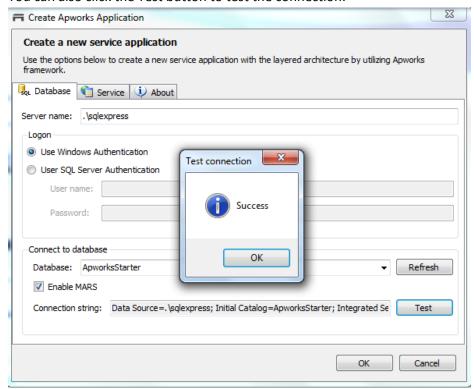

- About About the project template
- 2. Under the Database tab, select the SQL Server database you wish to use for the new application:

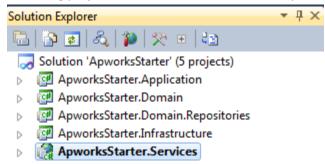

Make sure that the Enable MARS option is checked.

You can also click the Test button to test the connection:

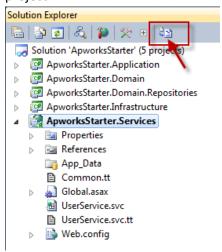

3. Under the Service tab, enter the proper namespace to use for the WCF service

- 4. Click OK button, Visual Studio will do the following tasks for you:
 - a. Create the Tables and Data in your selected database
 - Compile the entire solution This is required because the Text Templates under the generated Service project will need to use the compile output from other projects to generate the source code
- 5. Following projects will be created in Solution Explorer:

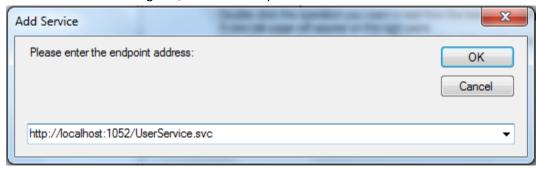

- ApworksStarter.Application The C# Class Library project that contains application interfaces and application service implementations
- ApworksStarter.Domain The C# Class Library project that contains the Domain Model, repository interfaces, specifications and O/R mapping schemas
- ApworksStarter.Domain.Repositories The C# Class Library that contains the repository implementations
- ApworksStarter.Infrastructure The C# Class Library that contains all the
 facilities at infrastructure level. Currently the project created by this project
 template only has a method extender class defined. You can add other utility
 classes here based on the requirement
- ApworksStarter.Services The WCF Service application which initializes the application and exposes the interfaces to the clients
- 6. Click the ApworksStarter.Services project in the Solution Explorer, then click Transform All Templates toolbox button, this will transform all the templates defined under this project:

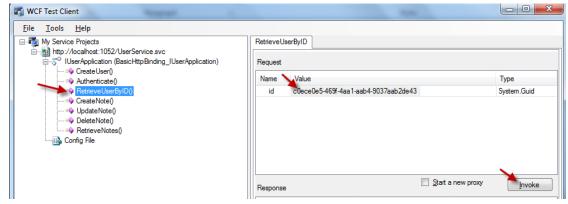

Transform result will be displayed in Visual Studio's Output window:

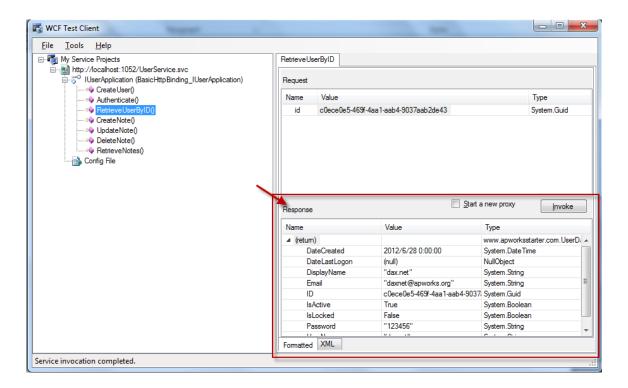

- 7. Press F5 to start the debugger
- 8. Start WCF Test Client
- 9. In WCF Test Client, click File -> Add Service menu, it will bring up the Add Service dialog box
- 10. In the Add Service dialog box, enter the endpoint address as follows:

11. Double click the RetrieveUserByID operation, in the Request panel, enter "c0ece0e5-469f-4aa1-aab4-9037aab2de43" for the "id" field, then click the Invoke button:

12. After the service has been called successfully, data will be displayed in the Response panel as below:

13. Now you can create your GUI project under the solution and invoke the service to provide functionalities

Layered Service Application (NHibernate)

This template will create the same sample application as the Layered Service Application (Entity Framework) does, except that this template will use the NHibernate as the repository implementation technology.

For other information about this project template, please refer to "Layered Service Application (Entity Framework)" in the above section.
